

Assumptions

For a Single Population Proportion Confidence Interval

Mark Rulkowski

Lecturer, Department of Statistics

Confidence Intervals

Best Estimate \pm Margin of Error

OR

Best Estimate \pm “a few” (estimated) standard errors

What are the assumptions?

- Best Estimate – in order to get a *reliable* best estimate, we need a ***SIMPLE RANDOM SAMPLE***
- Simple Random Sample – a representative subset of the population made up of observations (or subjects) that have an equal probability of being chosen

What are the assumptions?

- Margin of error – in order to use the critical z-value in our calculations, we need a ***large enough sample size***
- But what is ‘large enough’...?

What are the assumptions?

- Many viewpoints on what is deemed 'large enough'
- Regardless...

Larger Sample Size → Better Approximation

- For this course we will define 'large enough' as...
 - 10 of each outcome from the response group

Checking Assumptions

- Simple Random Sample – analyze how the sample was collected, does it seem representative?
- Large Enough Sample Size – do we have at least 10 of each outcome?

Confidence Intervals
